From Details 2/65

Exam Details

- When: Friday October 23, 3:35pm 5:35pm.
- This is a 2 hour, open book exam. Any material on myCourses (EPIB607/613) and personal notes are permitted.
- You are not permitted to use the internet and you must work alone.
 Using the internet or obtaining help from anyone else is considered
 Cheating as per Article 17 of the Code of Student Conduct and
 Disciplinary Procedures
- Provide units and state your assumptions when applicable. Label axes and write answers in complete sentences when appropriate.
- The format of the exam will follow the assignments. That is, you will be required to complete a series of questions in an RMarkdown document and knit to pdf. Your solutions for each question must then be uploaded to Crowdmark. A template will be provided.

You will be given 1 extra hour to upload your solutions.

Exam Details 3/65.

Topics to be covered

- Data visualization (histograms, boxplots, scatterplots, line plots), Tidy Data, Color Palettes
- 2. Descriptive statistics (mean, median, range, IQR, sd, correlation)
- 3. Normal Curve Calculations
- 4. Sampling Distributions, CLT, Bootstrap
- Confidence intervals and p-values for one sample mean and one sample proportion
- 6. Hypothesis Testing
- 7. Power and Sample size calculations

Exam Details 4/65 •

Data visualization 5/66

Aesthetics

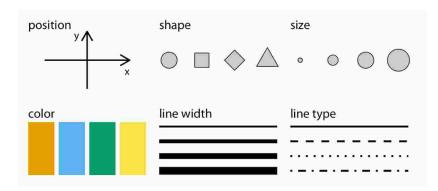

Aesthetics

Data visualization 6/65

Aesthetics

Aesthetics

 Commonly used aesthetics in data visualization: position, shape, size, color, line width, line type. Some of these aesthetics can represent both continuous and discrete data (position, size, line width, color) while others can only represent discrete data (shape, line type)

Oata visualization 6/65 •

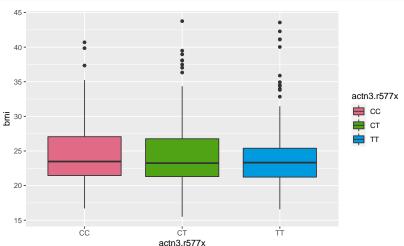

Types of Graphs

- Review the types of graphs created in the assignments.
- You should be able to critique a graph and propose appropriate graphics for a given dataset. Be mindful of the research question. The graphic should try to answer the research question.
- https://serialmentor.com/dataviz/ directory-of-visualizations.html
- https://www.data-to-viz.com/

Data visualization 7/65 •

Boxplots with qualitative palette

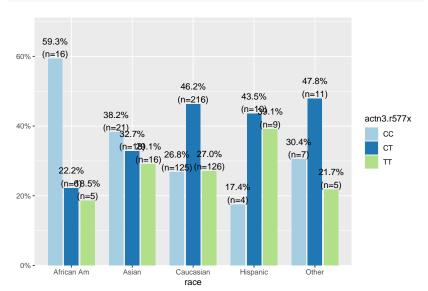

```
library(oibiostat); data("famuss")
library(ggplot2)
library(colorspace)
ggplot(famuss, aes(x = actn3.r577x, y = bmi, fill = actn3.r577x)) +
geom_boxplot() +
colorspace::scale_fill_discrete_qualitative()
```

Data visualization 8/65.

Conditional distribution of genotype given race

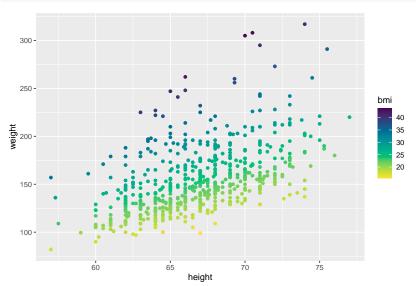

Data visualization 9/65.

Scatter plots with sequential palette

```
ggplot(famuss, aes(x = height, y = weight, color = bmi)) +
geom_point() +
colorspace::scale_color_continuous_sequential(palette = "Viridis")
```

Data visualization 10/65 •

Variable Types

- quantitative/numerical continuous (1.3, 5.7, 83, 1.5×10^{-2})
- quantitative/numerical discrete (1,2,3,4)
- qualitative/categorical unordered (dog, cat, fish)
- qualitative/categorical ordered (good, fair, poor)

Data visualization 11/65 .

```

Descriptive statistics 19/65.

Subsetting data

Descriptive statistics 20/65.

Standard error (SE) of a sample statistic

• Recall: When we are talking about the variability of a **statistic**, we use the term **standard error** (not standard deviation). The standard error of the sample mean is σ/\sqrt{n} .

Remark (SE vs. SD)

In quantifying the instability of the sample mean (\bar{y}) statistic, we talk of SE of the mean (SEM)

 $SE(\bar{y})$ describes how far \bar{y} could (typically) deviate from μ ;

SD(y) describes how far an individual y (typically) deviates from μ (or from \bar{y}).

Parameters, Samples, and Statistics

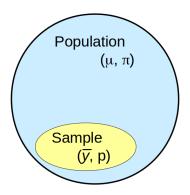

- Paramter: An unknown numerical constant pertaining to a population/universe, or in a statistical model.
 - \blacktriangleright μ : population mean π : population proportion
- **Statistic**: A numerical quantity calculated from a sample. The empirical counterpart of the parameter, used to *estimate* it.
 - $ightharpoonup ar{y}$: sample mean p: sample proportion

Parameters, Samples, and Statistics

- Paramter: An unknown numerical constant pertaining to a population/universe, or in a statistical model.

 - μ : population mean π : population proportion
- **Statistic**: A numerical quantity calculated from a sample. The empirical counterpart of the parameter, used to estimate it.
 - $\triangleright \bar{v}$: sample mean

p: sample proportion

Samples must be random

- The validity of inference will depend on the way that the sample was collected. If a sample was collected badly, no amount of statistical sophistication can rescue the study.
- Samples should be **random**. That is, there should be no systematic set
 of characteristics that is related to the scientific question of interest
 that causes some people to be more likely to be sampled than others.
 The simplest type of randomization selects members from the
 population with equal probability (a uniform distribution).

Samples must be random

- The validity of inference will depend on the way that the sample was collected. If a sample was collected badly, no amount of statistical sophistication can rescue the study.
- Samples should be random. That is, there should be no systematic set
 of characteristics that is related to the scientific question of interest
 that causes some people to be more likely to be sampled than others.
 The simplest type of randomization selects members from the
 population with equal probability (a uniform distribution).

Do not cheat by

- ► Taking 5 people from the <u>same</u> household to estimate
 - proportion of Québécois who don't have a family doctor
 - who saw a medical doctor last year
 - average rent
- ▶ Sampling the depth of the ocean <u>only around Montreal</u> to estimate
 - proportion of Earth's surface covered by water

Sampling Distributions

Definition (Sampling Distribution)

- The sampling distribution of a statistic is the distribution of values taken by the statistic in **all possible samples of the same size** from the same population.
- The standard deviation of a sampling distribution is called a standard error

Sampling Distributions

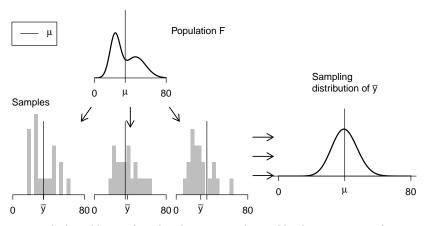

Figure: Ideal world. Sampling distributions are obtained by drawing repeated samples from the population, computing the statistic of interest for each, and collecting (an infinite number of) those statistics as the sampling distribution

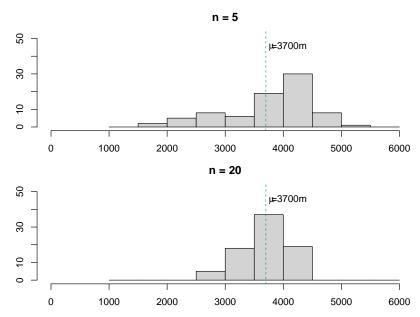

Why are sampling distributions important?

• They tell us how far from the target (true value of the parameter) our statistical <u>shot</u> at it (i.e. the statistic calculated form a sample) is likely to be, or, to have been.

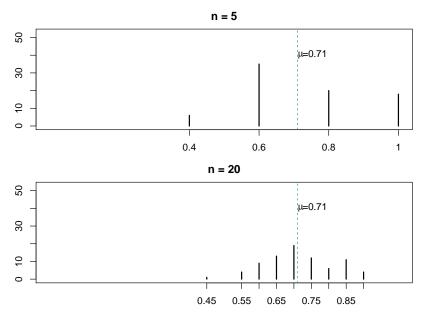

Why are sampling distributions important?

- They tell us how far from the target (true value of the parameter) our statistical <u>shot</u> at it (i.e. the statistic calculated form a sample) is likely to be, or, to have been.
- Thus, they are used in confidence intervals for parameters. Specific sampling distributions (based on a null value for the parameter) are also used in statistical tests of hypotheses.

Sampling distribution: mean depth of the ocean

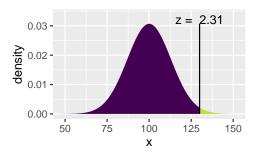

Sampling distribution: proportion covered by water

Normal Distribution: For probabilities we use *pnorm*

```
stats::pnorm(q = 130, mean = 100, sd = 13)
## [1] 0.99
```

```
mosaic::xpnorm(q = 130, mean = 100, sd = 13)
```

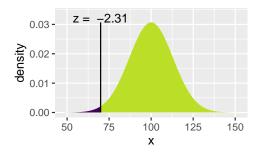

- ## [1] 0.99
 - pnorm returns the integral from $-\infty$ to q for a $\mathcal{N}(\mu, \sigma)$
 - pnorm goes from *quantiles* (think Z scores) to probabilities

Normal Distribution: For quantiles we use *qnorm*

```
stats::qnorm(p = 0.0104, mean = 100, sd = 13)
## [1] 70
```

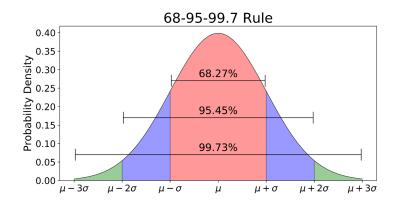

```
mosaic::xqnorm(p = 0.0104, mean = 100, sd = 13)
```

[1] 70

- qnorm answers the question: What is the Z-score of the pth percentile of the normal distribution?
- qnorm goes from probabilities to quantiles

Empirical Rule or 68-95-99.7% Rule

Quadruple the work, half the benefit

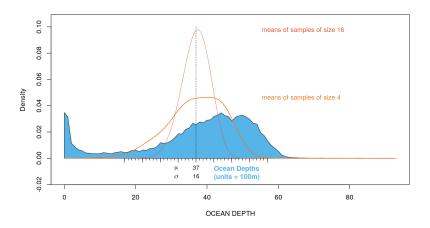

Figure: When the sample size increases from 4 to 16, the spread of the sampling distribution for the mean is reduced by a half, i.e., the range is cut in half. This is known as the curse of the \sqrt{n}

The Central Limit Theorem (CLT)

- The sampling distribution of \bar{y} is, for a large enough n, close to Gaussian in shape no matter what the shape of the distribution of individual Y values.
- This phenomenon is referred to as the CENTRAL LIMIT THEOREM
- The CLT applied also to a sample proportion, slope, correlation, or any other statistic created by aggregation of individual observations

Theorem (Central Limit Theorem)

if
$$Y \sim ???(\mu_Y, \sigma_Y)$$
, then

$$\bar{y} \sim \mathcal{N}(\mu_{Y}, \sigma_{Y}/\sqrt{n})$$

Confidence Interval

Definition (Confidence Interval)

A level C confidence interval for a parameter has two parts:

1. An interval calculated from the data, usually of the form

 $\textit{estimate} \pm \textit{margin of error}$

where the estimate is a sample statistic and the margin of error represents the accuracy of our guess for the parameter.

2. A confidence level C, which gives the probability that the interval will capture the true parameter value in different possible samples. That is, the confidence level is the success rate for the method

Confidence Interval: A simulation study

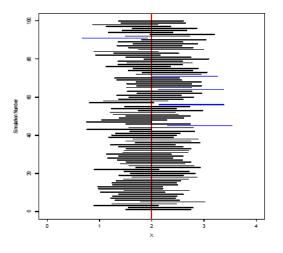

Figure: True parameter value is 2 (red line). Each horizontal black line represents a 95% CI from a sample and contains the true parameter value. The blue CIs do not contain the true parameter value. 95% of all samples give an interval that contains the population parameter.

Interpreting a frequentist confidence interval

 The confidence level is the success rate of the method that produces the interval.

Interpreting a frequentist confidence interval

- The confidence level is the success rate of the method that produces the interval.
- We don't know whether the 95% confidence interval from a particular sample is one of the 95% that capture θ (the unknown population parameter), or one of the unlucky 5% that miss.

Interpreting a frequentist confidence interval

- The confidence level is the success rate of the method that produces the interval.
- We don't know whether the 95% confidence interval from a particular sample is one of the 95% that capture θ (the unknown population parameter), or one of the unlucky 5% that miss.
- To say that we are 95% confident that the unknown value of θ lies between U and L is shorthand for "We got these numbers using a method that gives correct results 95% of the time."

68% Confidence interval using qnorm

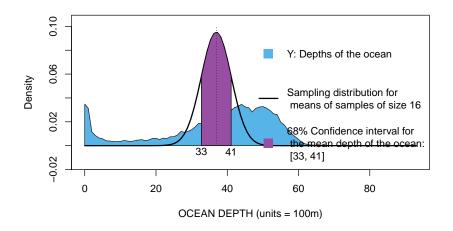

Figure: 68% Confidence interval calculated using qnorm(p = c(0.16,0.84), mean = 37, sd = 4.2)

95% Confidence interval using qnorm

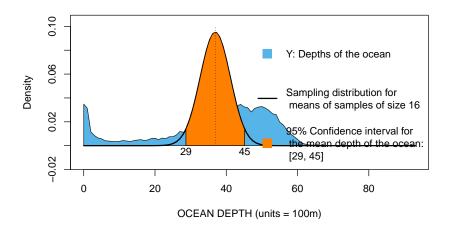

Figure: 95% Confidence interval calculated using qnorm(p = c(0.025,0.975), mean = 37, sd = 4.2)

Example: Inference for a single population mean

So what does the CI allow us to learn about μ ??

• It tells us that if we repeated this procedure again and again (collecting a sample mean, and constructing a 95% CI), 95% of the time, the CI would *cover* μ .

Example: Inference for a single population mean

So what does the CI allow us to learn about μ ??

- It tells us that if we repeated this procedure again and again (collecting a sample mean, and constructing a 95% CI), 95% of the time, the CI would *cover* μ .
- That is, with 95% probability, the *procedure* will include the true value of μ . Note that we are making a probability statement about the CI, not about the parameter.

Example: Inference for a single population mean

So what does the CI allow us to learn about μ ??

- It tells us that if we repeated this procedure again and again (collecting a sample mean, and constructing a 95% CI), 95% of the time, the CI would *cover* μ .
- That is, with 95% probability, the *procedure* will include the true value of μ . Note that we are making a probability statement about the CI, not about the parameter.
- Unfortunately, we do not know whether the true value of μ is contained in the CI in the particular experiment that we have performed.

A: Bootstrap

Bootstrap 42/65 •

Ideal world: known sampling distribution

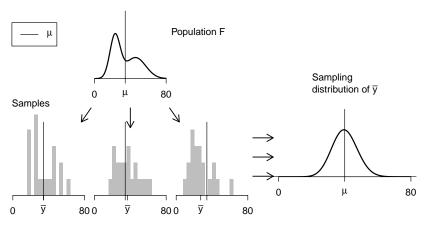

Figure: Ideal world. Sampling distributions are obtained by drawing repeated samples from the population, computing the statistic of interest for each, and collecting (an infinite number of) those statistics as the sampling distribution

Bootstrap 43/65 •

Reality: use the bootstrap distribution instead

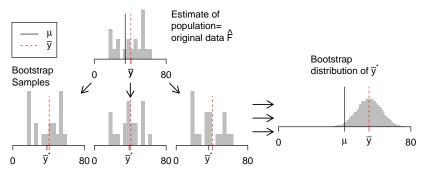

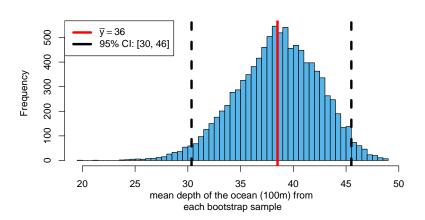

Figure: Bootstrap world. The bootstrap distribution is obtained by drawing repeated samples from an estimate of the population, computing the statistic of interest for each, and collecting those statistics. The distribution is centered at the observed statistic $(\bar{\gamma})$, not the parameter (μ) .

Bootstrap 44/65 ·

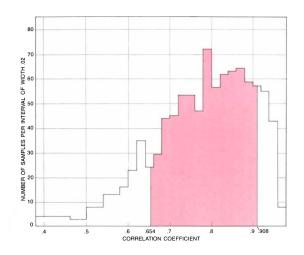

Main idea: simulate your own sampling distribution

```
R <- replicate(B, {
dplyr::sample_n(depths.n.20, size = N, replace = TRUE) %>%
dplyr::summarize(r = mean(alt)) %>%
dplyr::pull(r)
})
CI_95 <- quantile(R, probs = c(0.025, 0.975))
```

Bootstrap 45/65 •

Bootstrap can be used for other statistics (e.g. R^2)

p-value:

Power and sample size

n-values 52/65

p-values and statistical tests

Definition (*p*-value)

A probability concerning the observed data, calculated under a Null Hypothesis assumption, i.e., assuming that the only factor operating is sampling or measurement variation.

<u>Use</u> To assess the evidence provided by the sample data in relation to a pre-specified claim or 'hypothesis' concerning some parameter(s) or data-generating process.

<u>Basis</u> As with a confidence interval, it makes use of the concept of a *distribution*.

<u>Caution</u> A *p*-value is NOT the probability that the null 'hypothesis' is true

p-values 53/65 •

 The p-value is a probability concerning data, conditional on the Null Hypothesis being true.

p-values 54/65

- The p-value is a probability concerning data, conditional on the Null Hypothesis being true.
- It is not the probability that Null Hypothesis is true, conditional on the data.

p-values 54/65

- The p-value is a probability concerning data, conditional on the Null Hypothesis being true.
- It is not the probability that Null Hypothesis is true, conditional on the data.

 $p_{value} = P(\text{this or more extreme data}|H_0)$ $\neq P(H_0|\text{this or more extreme data}).$

p-values 54/65

- The p-value is a probability concerning data, conditional on the Null Hypothesis being true.
- It is not the probability that Null Hypothesis is true, conditional on the data.

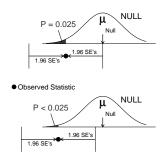

```
p_{value} = P(\text{this or more extreme data}|H_0)

\neq P(H_0|\text{this or more extreme data}).
```

- Statistical tests are often coded as statistically significant or not according to
 whether results are extreme or not with respect to a reference (null)
 distribution. But a test result is just one piece of data, and needs to be
 considered along with rest of evidence before coming to a 'conclusion.'
- Likewise with statistical 'tests': the *p*-value is just one more piece of *evidence*, hardly enough to 'conclude' anything.

p-values 54/65 •

Close relationship between *p*-value and CI

- (Upper graph) If upper limit of 95% CI *just touches* null value, then the 2 sided *p*-value is 0.05 (or 1 sided *p*-value is 0.025).
- (Lower graph) If upper limit excludes null value, then the 2 sided p-value is less than 0.05 (or 1 sided p-value is less than 0.025).
- (Graph not shown) If CI includes null value, then the 2-sided p-value is greater than (the
 conventional) 0.05, and thus observed statistic is "not statistically significantly different"
 from hypothesized null value.

p-values 55/65 •

Power and sample size

Power and sample size 56/65.

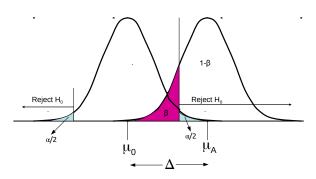

Power = $1 - \beta$

Definition (Power = $1 - \beta$)

The probability that a fixed level α significance test will reject H_0 when a particular alternative value of the parameter is true is called the **power** of the test to detect the alternative.

Distribution of \overline{y} under the null hypothesis:

Distribution of \overline{y} under an alternative hypothesis:

Power and sample size 57/65.

Power and Sample Size: 3 questions

1. How much water a supplier could add to the milk before they have a 10%, 50%, 80% chance of getting caught, i.e., of the buyer detecting the cheating ?

Power and sample size 58/65

Power and Sample Size: 3 questions

- 1. How much water a supplier could add to the milk before they have a 10%, 50%, 80% chance of getting caught, i.e., of the buyer detecting the cheating?
- 2. Assume a 99:1 mix of milk and water. What are the chances of detecting cheating if the buyer uses samples *n*=10, 15 or 20 rather than just 5 measurements?

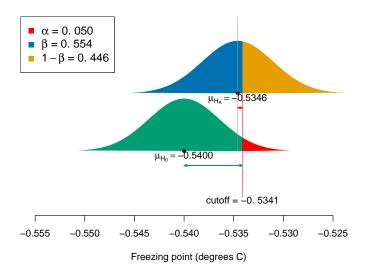

Power and sample size 58/65

Power and Sample Size: 3 questions

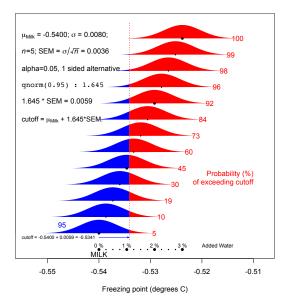

- 1. How much water a supplier could add to the milk before they have a 10%, 50%, 80% chance of getting caught, i.e., of the buyer detecting the cheating?
- 2. Assume a 99:1 mix of milk and water. What are the chances of detecting cheating if the buyer uses samples *n*=10, 15 or 20 rather than just 5 measurements?
- 3. At what n does the chance of detecting cheating reach 80%? (a commonly used, but arbitrary, criterion used in sample-size planning by investigators seeking funding for their proposed research)

Power and sample size 58/65.

If the supplier added 1% water to the milk

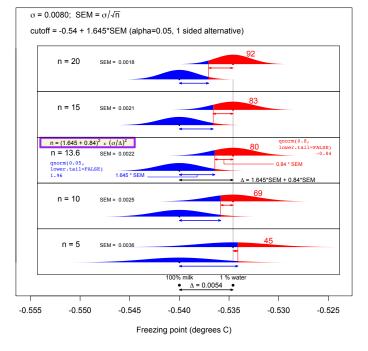

Power and sample size 59/65 .

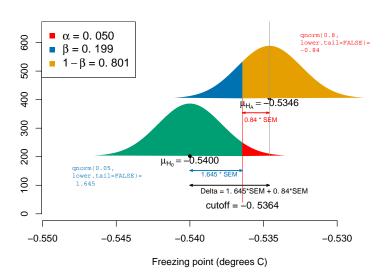

The probabilities in red were calculated using the formula: stats::pnorm(cutoff, mean = mu.mixture, sd = SEM, lower.tail=FALSE)

Power and sample size 60/65.

Power and sample size 61/65 .

The balancing formula

Power and sample size 62/65 .

What sample size needed?

• The 'balancing formula', in SEM terms, is simply the *n* where

$$1.645 \times SEM + 0.84 \times SEM = \Delta$$
.

Replacing each of the SEMs (assumed equal, because we assumed the variability is approx. the same under both scenarios) by σ/\sqrt{n} , i.e.,

$$1.645 \times \sigma/\sqrt{n} + 0.84 \times \sigma/\sqrt{n} = \Delta.$$

and solving for n, one gets

$$n = (1.645 + 0.84)^2 \times \left\{ \frac{\sigma}{\Delta} \right\}^2 = (1.645 + 0.84)^2 \times \left\{ \frac{\textit{Noise}}{\textit{Signal}} \right\}^2.$$

Power and sample size 63/65 •

What sample size needed? General Formula

• Two sided alternative:

$$\Delta = z_{1-\alpha/2} \times SEM + z_{1-\beta} \times SEM$$

One sided alternative:

$$\Delta = z_{1-\alpha} \times SEM + z_{1-\beta} \times SEM$$

Power and sample size 64/65.
